(Dated: February 2, 2008)

Abstract

We calculate the two-loop QCD corrections to paracharmonium decays $\eta_c \rightarrow \gamma\gamma$ and $\eta_c \rightarrow gg$ involving light-by-light scattering diagrams with light quark loops. Artificial large mass expansion and convergence improvement techniques are used to evaluate these corrections. The obtained corrections to the decays $\eta_c \rightarrow \gamma\gamma$ and $\eta_c \rightarrow gg$ account for -1.25% and -0.73% of the leading order contribution, respectively.

I. INTRODUCTION

Since the year 1974, when bound $c\bar{c}$ states (charmonium) were discovered, they have been thoroughly studied experimentally and theoretically, contributing to better knowledge of the Standard Model parameters. Generally, the theoretical description of charmonium decays requires the knowledge of the perturbative effects in $c\bar{c}$ annihilation, and non-perturbative corrections to the charmonium wave function. However, ratios of decay rates into different final states are only sensitive to perturbative QCD contributions. In the present paper we focus on the subset of two-loop perturbative corrections to the ground-state paracharmonium decays $\eta_c \rightarrow \gamma\gamma$ and $\eta_c \rightarrow gg$. Abelian $\mathcal{O}(\alpha_s)$ corrections to both decays are related to the one-loop correction to parapositronium decay by a trivial replacement of coupling constants [1]. Non-abelian one-loop contributions were presented in [2, 3]. $\mathcal{O}(\alpha_s^2)$ corrections to $\eta_c \rightarrow \gamma\gamma$ were discussed in [4], but those results did not include light-by-light scattering type contributions. Then we calculate these diagrams which form a gauge-independent subset.

Multiloop corrections in the perturbation theory can be calculated by the asymptotic expansion [5]. But at the present stage, it is impossible to calculate the two-loop diagrams considered in this paper by the ordinary asymptotic expansions because of the complexity of the diagrams. In order to calculate them we adopt the method of the large mass expansion (LME) [6, 7]. We introduce an artificial large mass M for the internal charm quarks and execute the asymptotic expansion with the mass scale of the external charm quarks m_c (soft scale) and the mass scale of the internal charm quarks M (hard scale). When the loop momenta of the internal charm quarks are factorized into the soft scale, we can expand the propagators of the charm quarks by the ratio m_c/M . The expansions of the propagators reduce the original diagrams to the simpler ones which we can calculate. After that we obtain the results in a series of m_c/M and identify the artificial mass M with the original one m_c .

The present paper is organized as follow. In Sec. II, we review the example of parapositronium decay $p\text{-Ps} \rightarrow \gamma\gamma$ to demonstrate the method of LME and obtain two-loop QED results. In Sec. III, we adapt the results in the $p\text{-Ps}$ decay to the paracharmonium decays $\eta_c \rightarrow \gamma\gamma$ and $\eta_c \rightarrow gg$, and obtain the two-loop QCD corrections by counting the color factors. In Sec. IV, we have a summary.

FIG. 1: Two diagrams which contribute to the p-Ps decay at tree level.

FIG. 2: Two diagrams M_1^{tree} and M_2^{tree} are shown.

II. PARAPOSITRONIUM DECAY

a. Tree-level decay rate Two diagrams in Fig. 1 contribute to the tree level decay. If we artificially set the mass of the internal propagator $M \gg m$ (with electron mass m), the total e^+e^- -annihilation cross section and the p-Ps decay rate are calculated in the low momentum limit as

$$\sigma_0(e^+e^- \rightarrow \gamma\gamma) = \frac{\pi r_0^2}{2\beta} \frac{4r^4}{(1+r^2)^2}, \quad (1)$$

$$\Gamma(\text{p-Ps} \rightarrow \gamma\gamma) = (2\beta) \cdot 4\sigma_0(e^+e^- \rightarrow \gamma\gamma) \cdot |\psi(0)|^2, \quad (2)$$

where β is the electron velocity, $r_0 = \alpha_e/m$, and $r = m/M$. Here the value of the positronium wave function at the origin is $|\psi(0)|^2 = 1/\pi(2a_0)^3$ with $a_0 = 1/(m\alpha_e)$. Making $r = 1$, we obtain the well known p-Ps decay rate at the tree level. The same result can be obtained using the optical theorem:

$$\sigma_0(e^-e^+ \rightarrow \gamma\gamma) = \frac{1}{4\beta m^2} \text{Im}[M_1^{tree} + M_2^{tree}], \quad (3)$$

where two diagrams M_1^{tree} and M_2^{tree} are shown in Fig. 2. However, we here expand the Wick rotated propagator by a large mass M before the loop integral as $1/(l^2 + M^2) = \sum_{n=0}^{\infty} (-l^2)^n / M^{2(n+1)}$. The right hand side of Eq. (3) is calculated as

$$\text{Im}[M_1^{tree} + M_2^{tree}] = \pi\alpha_e^2(8r^4 - 16r^6 + \dots), \quad (4)$$

which coincides with the first terms in the expansion of Eq. (1). We introduce the gauge parameter in the photon propagator to check the gauge symmetry. In general the introduction

FIG. 3: Three diagrams M_1, M_2 and M_3 are shown.

of the artificial mass M breaks the gauge symmetry, namely, the Ward-Takahashi identity. However, when both of electron and positron rest, the gauge symmetry is restored and the result in Eq. (4) does not depend on gauge parameter.

b. Two-loop correction We proceed to two-loop contributions involving light-by-light scattering diagrams. We calculate the corrections $\Delta\sigma$ to the leading order cross section σ_0 through the optical theorem:

$$\Delta\sigma = \frac{1}{2\beta m^2} \cdot \text{Im}[M_1 + M_2 + M_3], \quad (5)$$

where the three-loop diagrams M_1, M_2 , and M_3 are shown in Fig. 3. Here the internal fermion loop is considered massless, while the case of electron in the internal loop has been considered in [8]. The sum of imaginary parts of these diagrams is gauge-independent. For divergences, we employ the dimensional regularization with $D = 4 - 2\epsilon$. The diagrams with inverse orientation of the fermion loop exist and their contributions are same. Assigning the artificial large mass to the two internal electron propagators, we now have to consider several possibilities for the loop momentum scales. In the case of diagram M_1 , for example, we take p_3, p_7 , and p_{12} as the three independent loop momenta and the following four regions exist : 1. $p_3 \ll M, p_7 \ll M, p_{12} \ll M$, 2. $p_3 \simeq M, p_7 \ll M, p_{12} \ll M$, 3. $p_3 \simeq M, p_7 \simeq M, p_{12} \ll M$, and 4. $p_3 \simeq M, p_7 \ll M, p_{12} \simeq M$. To calculate the hardest three-loop integrals in region 1 (all soft momenta), we use the MINCER package [9] and the factorized integrals are calculated in FORM [10] using well-known formulae. Although each of $\text{Im}[M_1]$ and $\text{Im}[M_2]$ has the divergences of $1/\epsilon$ and depends on gauge parameter, the sum is free from divergences and gauge parameter. We can obtain it up to the first eight terms:

$$\text{Im}[M_1 + M_2] \cdot \frac{\pi}{\alpha^4} = +r^4(-0.394 + 4 \log r) + r^6(0.121 - 8 \log r)$$

$$\begin{aligned}
& + r^8(0.113 + 12.3 \log r) + r^{10}(-0.316 - 16.9 \log r) \\
& + r^{12}(0.481 + 21.7 \log r) + r^{14}(-0.618 - 26.7 \log r) \\
& + r^{16}(0.734 + 31.9 \log r) + r^{18}(-0.834 - 37.3 \log r).
\end{aligned} \tag{6}$$

Here and hereafter only three digits in the coefficients are shown. $\text{Im}[M_3]$ can be calculated up to the first six terms:

$$\begin{aligned}
\text{Im}[M_3] \cdot \frac{\pi}{\alpha^4} = & + r^4(-0.313 + 8 \log r) + r^6(-0.706 - 16 \log r) \\
& + r^8(1.40 + 25.0 \log r) + r^{10}(-1.93 - 34.8 \log r) \\
& + r^{12}(2.31 + 45.2 \log r) + r^{14}(-2.62 - 56.1 \log r).
\end{aligned} \tag{7}$$

$\text{Im}[M_3]$ is gauge invariant in itself and has no divergence. The series in Eqs. (6) and (7) apparently do not converge at $r = 1$. However, we can choose an expansion parameter z instead of r such that these series converge. The comparison between Eqs. (1) and (4) suggests an appropriate substitution,

$$z = \frac{2r^2}{1 + r^2}. \tag{8}$$

The change of the variable reconstructs the series in Eq. (6) into the following series of z ,

$$\begin{aligned}
\text{Im}[M_1 + M_2] \cdot \frac{\pi}{\alpha^4} = & + z^2(-0.445 + 0.5 \log z) + z^3(0.166) \\
& + z^4(0.0108 + 0.0111 \log z) + z^5(-0.000899 + 0.00740 \log z) \\
& + z^6(-0.00156 + 0.00462 \log z) + z^7(-0.00110 + 0.00297 \log z) \\
& + z^8(-0.000690 + 0.00198 \log z) + z^9(-0.000421 + 0.00137 \log z),
\end{aligned} \tag{9}$$

which are good convergent series. The series in Eq. (7) are also converted to good convergent series of z . Since the obtained series are limited in the first several terms, we should estimate the errors with the remaining infinite series. We rewrite the series in Eq. (9) as $\sum_{i=2}^{\infty} c_i z^i$ and estimate the errors as $\left| \sum_{i=10}^{\infty} c_i \right| < |c_9| \sum_{i=1}^{\infty} t^i$. Here we can conservatively set $t = 0.62$ because of the ratio $c_9/c_8 \simeq 0.610$. We can obtain the result,

$$\text{Im}[M_1 + M_2] \cdot \frac{\pi}{\alpha^4} = \left(\sum_{i=2}^9 c_i + \frac{tc_9}{2(1-t)} \right) \pm \frac{t|c_9|}{2(1-t)} \tag{10}$$

$$= -0.2726 \pm 0.00034 (\equiv d_{12}), \tag{11}$$

FIG. 4: Diagram corresponding to M_1 in Fig. 3 for the decay $\eta_c \rightarrow \gamma\gamma$ ($\eta_c \rightarrow gg$) is shown in the left (right).

where we write this result as d_{12} for the latter references. In the same way, we can obtain the results,

$$\text{Im}[M_3] \cdot \frac{\pi}{\alpha^4} = -0.4692 \pm 0.0029 (\equiv d_3). \quad (12)$$

$$\text{Im}[M_1 + M_2 + M_3] \cdot \frac{\pi}{\alpha^4} = -0.7419 \pm 0.0033 (\equiv d_{tot}). \quad (13)$$

We check that the results in Eqs. (11) and (12) are supported by the results of two summation methods, Hölder summation and Shanks transformation.

III. CHARMONIUM DECAY

c. Paracharmonium decays to photons The decay rate is given in the analogous form to Eq. (2) as

$$\Gamma(\eta_c \rightarrow \gamma\gamma) = (2\beta) \cdot 4\sigma_{tot}(c\bar{c} \rightarrow \gamma\gamma) \cdot |\psi_c(0)|^2, \quad (14)$$

where ψ_c is the charmonium wave function. The tree-level decay rate is $\Gamma_0(\eta_c \rightarrow \gamma\gamma) = 4\pi\alpha_e^2(Q_c)^4 N_c |\psi_c(0)|^2 / m_c^2$ with the charm mass m_c , the electric charge of the charm quark Q_c , and $N_c = 3$. We here use the color singlet wave function for η_c ,

$$|\eta_c\rangle = \frac{1}{\sqrt{N_c}} \delta_{ij} |c^i \bar{c}^j\rangle, \quad (15)$$

where i and j are the color indices. Two-loop QCD corrections have the three diagrams corresponding to M_1 , M_2 and M_3 in Fig. 3. Diagram $M_1(c\bar{c} \rightarrow c\bar{c})$ corresponding to M_1 is shown in the left in Fig. 4, where t^a is the generators of QCD. We restrict the quarks running in the fermion loop to the up, down, and strange quarks which can be regarded as massless. We can obtain $\text{Im}[M_1(c\bar{c} \rightarrow c\bar{c})]$, counting the extra factors relative to $\text{Im}[M_1(e^-e^+ \rightarrow e^-e^+)]$, as

$$\frac{\text{Im}[M_1(c\bar{c} \rightarrow c\bar{c})]}{\text{Im}[M_1(e^-e^+ \rightarrow e^-e^+)]} = \left(\frac{\alpha_s}{\alpha_e}\right)^2 (Q_c)^2 [(Q_u)^2 + (Q_d)^2 + (Q_s)^2] \cdot T_R^2 (N_c^2 - 1), \quad (16)$$

where α_s is the strong coupling constant and $T_R = 1/2$. The extracted factors in Eq. (16) are common to the diagram where the orientation of the fermion loop is reversed in Fig. 4 and they are also common to the other two diagrams corresponding to M_2 and M_3 in Fig. 3. Then, using Eqs. (5), (14) and (16) with $Q_u = Q_c = 2/3$ and $Q_d = Q_s = -1/3$, we obtain the decay rate including the two-loop corrections as

$$\Gamma(\eta_c \rightarrow \gamma\gamma) = \Gamma_0(\eta_c \rightarrow \gamma\gamma) \left[1 + \left(\frac{\alpha_s}{\pi} \right)^2 d_{tot} \right]. \quad (17)$$

d. Paracharmonium decays to gluons The decay rate is obtained by the formula analogous to Eq. (14). The tree-level decay rate is $\Gamma_0(\eta_c \rightarrow gg) = 8\pi\alpha_s^2 T_R^2 C_F |\psi_c(0)|^2 / m_c^2$ with $C_F = 4/3$. Three diagrams which correspond to three in Fig. 3 contribute to the two-loop QCD corrections. Diagram $M_1(c\bar{c} \rightarrow c\bar{c})$ is the right one in Fig. 4. Using the wave function in Eq. (15), we obtain the common extra factors for $M_{1,2}(e^-e^+ \rightarrow e^-e^+)$ as

$$\text{Im}[M_{1,2}(c\bar{c} \rightarrow c\bar{c})] = \text{Im}[M_{1,2}(e^-e^+ \rightarrow e^-e^+)] \cdot T_R^2 C_F^2 n_q, \quad (18)$$

where n_q is the number of the light quarks. The color factor for M_3 is different from one for M_1 and M_2 , as $T_R^2 C_F (C_F - C_A/2) n_q$ with $C_A = 3$. Thus, we obtain the decay rate as

$$\Gamma(\eta_c \rightarrow gg) = \Gamma_0(\eta_c \rightarrow gg) \left[1 + \left(\frac{\alpha_s}{\pi} \right)^2 \frac{n_q}{2} \left(C_F d_{tot} - \frac{1}{2} C_A d_3 \right) \right]. \quad (19)$$

It should be noted that if we average the colors of the charm and anti-charm quarks in this calculation, the divergences are not cancelled because the color factors for M_1 and M_2 are different as $\text{Tr}[t^a t^b t^c t^d] \text{Tr}[t^a t^d t^c t^b] \neq \text{Tr}[t^a t^b t^c t^d] \text{Tr}[t^a t^d t^b t^c]$. The QCD bare lagrangian has the gluon four-point interaction, unlike QED, and the gluon four-point function has divergences proportional to the interaction term in the bare lagrangian. However, the requirement that η_c is color singlet state in Eq. (15) reduces the color factors for M_1 and M_2 from the different ones to the common ones in Eq. (18) and eliminates the potential divergences in the two-loop QCD corrections.

e. Numerical values of corrections We first estimate the corrections in $\eta_c \rightarrow \gamma\gamma$ as

$$\Gamma(\eta_c \rightarrow \gamma\gamma) = \Gamma_0(\eta_c \rightarrow \gamma\gamma) \left[1 + \left(\frac{\alpha_s}{\pi} \right) \delta_\gamma^{(1)} + \left(\frac{\alpha_s}{\pi} \right)^2 \delta_\gamma^{(2)} \right] \quad (20)$$

$$= \Gamma_0(\eta_c \rightarrow \gamma\gamma) [1 + (-0.439) + (-0.0125 + 0.017 \cdot \delta_\gamma^{others})]. \quad (21)$$

Here we use the values of the one-loop corrections $\delta_\gamma^{(1)} \simeq -3.38$ [1, 11] and the two-loop corrections are written as $\delta_\gamma^{(2)} = d_{tot} + \delta_\gamma^{other}$ from Eq. (17). δ_γ^{other} denotes the other two-loop corrections. We also use the coupling constant at the scale of the charm quark mass,

$\alpha_s(m_c) = 0.41$ [12]. We find that the obtained two-loop corrections account for -1.25% of the tree-level decay rate, neglecting the uncertainty of d_{tot} in Eq. (13) due to its smallness. We next estimate the corrections in $\eta_c \rightarrow gg$ in the same way:

$$\Gamma(\eta_c \rightarrow gg) = \Gamma_0(\eta_c \rightarrow gg)[1 + (0.633) + (-0.00729 + 0.017 \cdot \delta_g^{others})]. \quad (22)$$

where in the analogue to Eq. (20), the one-loop correction is $\delta_g^{(1)} \simeq 4.87$ [2, 3, 11]. The two-loop correction is $\delta_g^{(2)} = n_q(C_F d_{tot} - C_A d_3/2)/2 + \delta_g^{other}$ from Eq. (19). The obtained corrections account for -0.73% of the tree level. The ratio of the decay rates in Eq. (21) to one in Eq. (22) is free from the ambiguity of the wave function $\psi_c(0)$. To compare the ratio to the experimental value, we need the other corrections δ_γ^{others} and δ_g^{others} , which we leave for future work.

IV. SUMMARY

We calculate the two-loop QCD corrections to the decay modes $\eta_c \rightarrow \gamma\gamma$ and $\eta_c \rightarrow gg$ involving light-by-light scattering diagrams with light quark loops by the method of LME. The obtained series in LME are transformed into ones with good convergence properties by a change of the expansion parameter. The obtained corrections to the decay $\eta_c \rightarrow \gamma\gamma$ account for -1.25% of the tree-level and the corrections to $\eta_c \rightarrow gg$ account for -0.73% . The artificially introduced large mass does not break the gauge symmetry in the kinematic case of both initial particles at rest because the results are independent of the gauge parameter. Regarding the divergences of the two-loop QCD corrections to $\eta_c \rightarrow gg$ in the present paper, the nature that the observed hadron, η_c in this case, is color singlet state, eliminates the potential divergences.
